## Relational Design Theory

Carla Teixeira Lopes

Bases de Dados Mestrado Integrado em Engenharia Informática e Computação, FEUP

Based on Jennifer Widom and Christopher Ré slides

## Agenda

Relational Design Overview

**Functional Dependencies** 

Closures, Superkeys and Keys

Inferring Functional Dependencies

**Normal Forms** 

Decompositions

### Relational Design

#### Designing a database schema

Usually many designs possible Some are (much) better than others! How do we choose?

#### Often use higher-level design tools, but ...

Some designers go straight to relations Useful to understand why tools produce certain schemas

Design theory is about how to represent your data to avoid anomalies.

#### College application info

SSN and name

Colleges applying to

High schools attended (with city)

Hobbies

Apply (SSN, sName, cName, HS, HScity, hobby)

#### Apply(SSN, sName, cName, HS, HScity, hobby)

123 Ann from Palo Alto High School (PAHS) and Gunn High School (GHS) also in Palo Alto plays tennis and trumpet and applied to Stanford, Berkeley, and MIT

#### Apply

SSN	sName	cName	HS	HScity	hobby
123	Ann	Stanford	PAHS	Palo Alto	tennis
123	Ann	Stanford	PAHS	Palo Alto	trumpet
123	Ann	Berkeley	PAHS	Palo Alto	trumpet
				•	
•	•	•	•	•	

12 tuples

### Design Anomalies: Redundancy

Capture information multiple times

How many times do we capture the fact that

123 is the social security number of Ann?

she plays tennis?

she applied to MIT?

Apply

SSN	sName	cName	HS	HScity	hobby
123	Ann	Stanford	PAHS	Palo Alto	tennis
123	Ann	Stanford	PAHS	Palo Alto	trumpet
123	Ann	Berkeley	PAHS	Palo Alto	trumpet
		•		•	
•	•		•	•	•

#### Design Anomalies: Update Anomaly

Direct effect of redundancy

Can update facts in some places but not all or differently in different places

trumpet -> piano

#### Apply

sName	cName	HS	HScity	hobby
Ann	Stanford	PAHS	Palo Alto	tennis
Ann	Stanford	PAHS	Palo Alto	piano
Ann	Berkeley	PAHS	Palo Alto	trumpet
•			•	
•	•	•	•	•
	Ann Ann Ann	Ann Stanford Ann Stanford Ann Berkeley .	Ann Stanford PAHS Ann Stanford PAHS Ann Berkeley PAHS	Ann Stanford PAHS Palo Alto Ann Stanford PAHS Palo Alto Ann Berkeley PAHS Palo Alto

#### Design Anomalies: Deletion Anomaly

#### Inadvertently deletion

#### Example

1 new tuple about John

Someone decides surfing is an unacceptable hobby and delete the tuples about surfing

Students with surfing as their only hobby will be deleted completed

#### Apply

SSN	sName	cName	HS	HScity	hobby
123	Ann	Stanford	PAHS	Palo Alto	trumpet
123	Ann	Berkeley	PAHS	Palo Alto	trumpet
				•	
234	John	MIT	PAHS	Palo Alto	surfing

#### Example: New Design

#### College application info

SSN and name / Colleges applying to / High schools attended (with city) / Hobbies

#### What about this design?

Student (SSN, sName) Apply (SSN, cName)

HighSchool (SSN, HS)

Located (HS, HScity)

Hobbies (SSN, hobby)

No redundancy No update or deletion anomalies Reconstruction of original data

We'll understand why this design is better and learn how to find this decomposition

### Example: Modifications to the New Design

What if the high school name alone is not a key?

Student (SSN, sName)

Apply (SSN, cName)

HighSchool (SSN, HS)

Located (HS, HScity)

Hobbies (SSN, hobby)

Student (SSN, sName)

Apply (SSN, cName)

HighSchool (SSN, HS, HScity)

Located (HS, HScity)

Hobbies (SSN, hobby)

### Example: Modifications to the New Design

What if students don't want all of their hobbies revealed to all of the colleges?

Student (SSN, sName)

Apply (SSN, cName)

HighSchool (SSN, HS, HScity)

Located (HS, HScity)

Hobbies (SSN, hobby)

Student (SSN, sName)

Apply (SSN, cName, hobby)

HighSchool (SSN, HS, HScity)

Located (HS, HScity)

Hobbies (SSN, hobby)

The best design also depends in what the data is representing in the real world

### Design by decomposition

Start with "mega" relations containing everything

Decompose into smaller, better relations with same information

Decomposition can be done automatically **Functional** "Mega" relations + properties of the data dependencies System decomposes based on properties Final set of relations satisfies normal form

No anomalies, no lost information

### Agenda

Relational Design Overview

**Functional Dependencies** 

Closures, Superkeys and Keys

Inferring Functional Dependencies

**Normal Forms** 

Decompositions

## Functional Dependencies (FD)

#### Generalization of the notion of keys

#### Relational design by decomposition

To design a better schema, one which minimizes the possibility of anomalies

#### Data storage

Compression schemes based on functional dependencies can be used

# Reasoning about queries Optimization of queries

Student (SSN, sName, address, HScode, HSname, HScity, GPA, priority)

Suppose priority is determined by GPA

GPA>3.8  $\rightarrow$  priority=1 3.3<GPA<=3.8  $\rightarrow$  priority=2 GPA<=3.3  $\rightarrow$  priority=3

Two tuples with same GPA have same priority

Student (SSN, sName, address, HScode, HSname, HScity, GPA, priority)

Two tuples with same GPA have same priority

 $\forall t, u \in Student: t. GPA = u. GPA \Rightarrow t. priority = u. priority$ 

GPA -> priority

#### Definition

A and B are attributes of a relation R

A -> B

A functionally determines B

 $\forall t, u \in R: t.A = u.A \Rightarrow t.B = u.B$ 

#### Definition

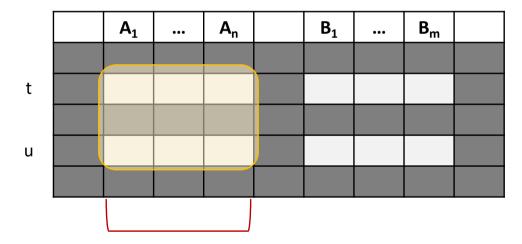

A<sub>1</sub>, A<sub>2</sub>, ..., A<sub>n</sub> and B<sub>1</sub>, B<sub>2</sub>, ..., B<sub>m</sub> are attributes of a relation R

$$A_1, A_2, ..., A_n \rightarrow B_1, B_2, ..., B_m$$
 $\bar{A}$ 
 $\bar{B}$ 

 $\forall \ t,u \in R: t[A1,\ldots,An] = u[A1,\ldots,An] \Rightarrow t. \ [B1,\ldots,Bm] = u. \ [B1,\ldots,Bm]$ 

#### A Picture of FDs

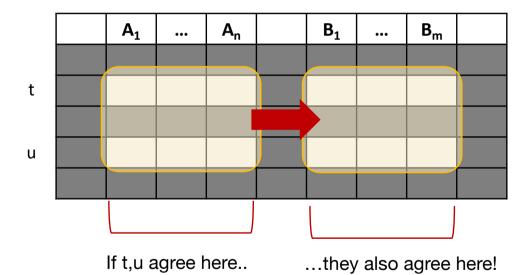

$$\forall t, u \in R: t[A1, ..., An] = u[A1, ..., An] \Rightarrow t. [B1, ..., Bm] = u. [B1, ..., Bm]$$

If t,u agree here..

#### A Picture of FDs

$$\forall t, u \in R: t[A1, ..., An] = u[A1, ..., An] \Rightarrow t. [B1, ..., Bm] = u. [B1, ..., Bm]$$

## Identifying FDs

Based on knowledge of real world

All instances of relation must adhere

You can check if an FD is violated by examining a single instance

However, you cannot prove that an FD is part of the schema by examining a single instance

This would require checking every valid instance

EmpID	Name	Phone	Position
E0045	Smith	1234	Clerk
E3542	Mike	9876	Salesrep
E1111	Smith	9876	Salesrep
E9999	Mary	1234	Lawyer

What functional dependencies do you identify?

EmpID	Name	Phone	Position
E0045	Smith	1234	Clerk
E3542	Mike	9876 ←	Salesrep
E1111	Smith	9876 ←	Salesrep
E9999	Mary	1234	Lawyer

{Position} → {Phone}

EmpID	Name	Phone	Position
E0045	Smith	1234 →	Clerk
E3542	Mike	9876	Salesrep
E1111	Smith	9876	Salesrep
E9999	Mary	1234 →	Lawyer

but not {Phone} → {Position}

Student (SSN, sName, address, HScode, HSname, HScity, GPA, priority)

SSN -> sName

SSN -> address

HScode -> HSname, HScity

HSname, HScity -> HScode \_\_\_\_\_

SSN -> GPA

GPA -> priority

SSN -> priority

Assuming the student doesn't move

No two high schools with the same name in the same city

Apply (SSN, cName, state, date, major)

cName -> date

Assuming every college has a single date to receive applications

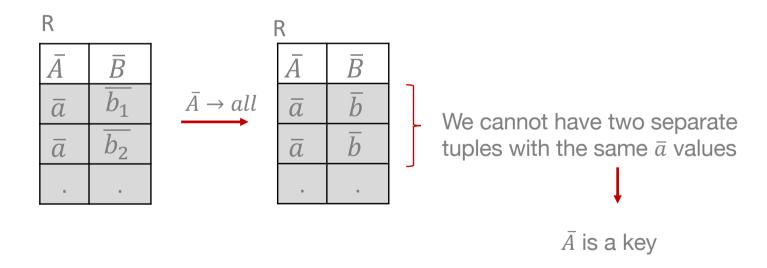

Assuming students are only allowed to apply to a single major at each college

Depends on the real world constraints

## Keys

Relation with no duplicates:  $R(\overline{A}, \overline{B})$ 

If  $\bar{A}$  -> all attributes then  $\bar{A}$  is a key

#### Trivial Functional Dependency

 $\bar{A} \to \bar{B}$  is a trivial dependency if  $\bar{B} \subseteq \bar{A}$ 

R		
	Ā	
	•	0
	0	
	•	
$ar{B}$		

It's obvious that, if  $\bar{A}$  has the same values, then  $\bar{B}$  will have the same values

#### Nontrivial Functional Dependency

A functional dependency that's not a trivial one

 $\bar{A} \to \bar{B}$  is a nontrivial dependency if  $\bar{B} \nsubseteq \bar{A}$ 

R			
	$\bar{A}$		
•			•
			•
•			 
			J
	Ì	<del>-</del> B	

Now the FD is saying something

## Completely Nontrivial Functional Dependency

A functional dependency that's not a trivial one

 $\bar{A} \to \bar{B}$  is a completely nontrivial dependency if  $\bar{A} \cap \bar{B} = \emptyset$ 

R		
$\bar{A}$	$ar{B}$	
0		
0		
•		

These are the ones we're most interested in

## Finding Functional Dependencies

Given a set of FDs,  $F = \{f_1, ..., f_n\}$ , does an FD g hold?

How do we decide?

Using rules

Splitting/Combining, Trivial and Transitivity

## Splitting Rule

We can split the right side of the FD

$$\bar{A} \to B_1, B_2, \dots, B_n \Rightarrow \bar{A} \to B_1, \bar{A} \to B_2, \dots, \bar{A} \to B_n$$

Can we also split left-hand-side?

$$A_1, A_2, \dots, A_n \to \overline{B} \Rightarrow A_1 \to \overline{B}, A_2 \to \overline{B}, \dots, A_2 \to \overline{B}$$
?

#### No, for example

HSname, HScity -> HScode

HSname -> HScode

HScity -> HScode

### Combining Rule

Inverse of the splitting rule

$$\bar{A} \to B_1, \bar{A} \to B_2, \dots, \bar{A} \to B_n \Rightarrow \bar{A} \to B_1, B_2, \dots, B_n$$

#### Trivial-dependency rules

Reminder:  $\bar{A} \to \bar{B}$  is a trivial dependency if  $\bar{B} \subseteq \bar{A}$ Every left hand side determines itself or any subset of itself

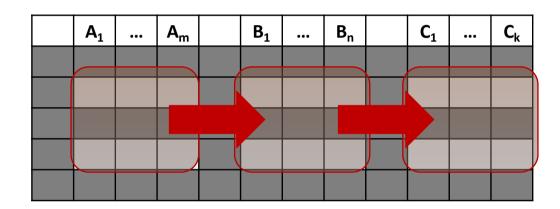

$$\bar{A} \to \bar{B} \implies \bar{A} \to \bar{A} \cup \bar{B}$$

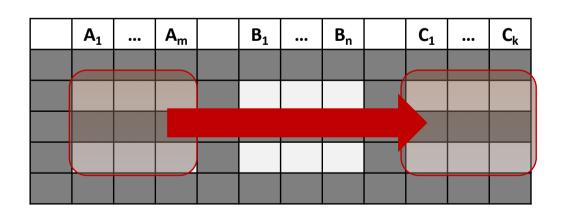

We can add to the right side of every FD what's already on the left hand side

$$\bar{A} \to \bar{B} \ \Rightarrow \bar{A} \to \bar{A} \cap \bar{B}$$
 Also implied by the splitting rule

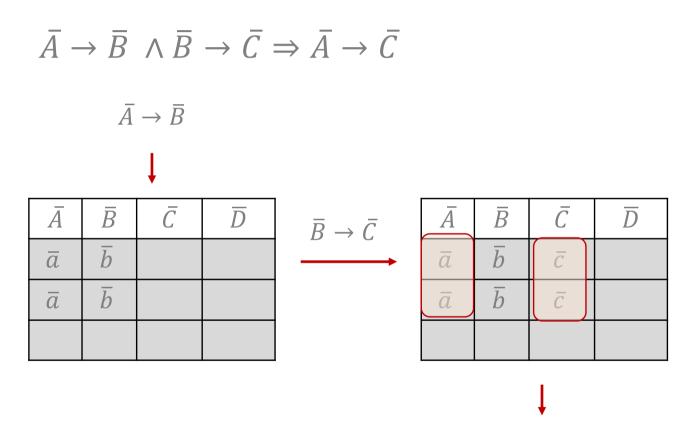

#### Transitive Rule

$$\bar{A} \to \bar{B} \wedge \bar{B} \to \bar{C} \Rightarrow \bar{A} \to \bar{C}$$

#### Transitive Rule

Shows that  $\bar{A} \to \bar{C}$  holds

## Finding Functional Dependencies

#### **Products**

Name	Color	Category	Dep	Price
Gizmo	Green	Gadget	Toys	49
Widget	Black	Gadget	Toys	59
Gizmo	Green	Whatsit	Garden	99

#### Provided FDs

- 1. {Name} -> {Color}
- 2. {Category} -> {Department}
- 3. {Color, Category} -> {Price}

Inferred FD	Rule used
4. {Name, Category} -> {Name}	?
5. {Name, Category} -> {Color}	?
6. {Name, Category} -> {Category}	?
7. {Name, Category} -> {Color, Category}	?
8. {Name, Category} -> {Price}	?

## Finding Functional Dependencies

#### **Products**

Name	Color	Category	Dep	Price
Gizmo	Green	Gadget	Toys	49
Widget	Black	Gadget	Toys	59
Gizmo	Green	Whatsit	Garden	99

#### Provided FDs

- 1. {Name} -> {Color}
- 2. {Category} -> {Department}
- 3. {Color, Category} -> {Price}

Inferred FD	Rule used	
4. {Name, Category} -> {Name}	Trivial	
5. {Name, Category} -> {Color}	Transitive (4, 1)	
6. {Name, Category} -> {Category}	Trivial	
7. {Name, Category} -> {Color, Category}	Combining rule (5, 6)	
8. {Name, Category} -> {Price}	Transitive (7, 3)	

#### Kahoot time!

Any doubts?

### Readings

# Jeffrey Ullman, Jennifer Widom, A first course in Database Systems 3<sup>rd</sup> Edition

Section 3.1 – Functional Dependencies

Section 3.2 – Rules About Functional Dependencies

Section 3.3 – Design of Relational Database Schemas

Section 3.4 – Decomposition: The Good, Bad, and Ugly

Section 3.5 – Third Normal Form
